### Description of the communication protocol to the Positive Grid Spark 40 amplifier

By Paul Hamshere with a great acknowledgement to Yury Tsybizov (ytsibizov) and Justin Nelson (jrnelson). Thanks to Ian McKellar for pointing out the MIDI SysEx similarity and that the packed data format is actually based on msgpack (www.msgpack.org)

#### Overview of communication

The Spark 40 amplifier communicates with the Spark app over Bluetooth. This seems to be 'serial bluetooth' for the Android app and 'BLE' for iOS.

The app sends messages to change preset, change an effect, change the parameter for an effect (eg gain). It can also request the details of each hardware preset, the name of the amp and the serial number.

In return, the amp will send messages when one of the presets is changed or when a knob is moved. This allows the app to mimic the settings on the amp at all points.

When the app starts, it asks the Spark for its name, serial number and all four hardware presets.

Then communication is event driven - either from the app or the amp.

#### Overview of message format

The bluetooth messages are exchanged in a specific data format. The terminology below is one I created to help understand the underlying structure.

Messages are exchanged in blocks. Each block contains one or more chunks. Each chunk contains data - which is all, or part of, the message.

Blocks and chunks appear to have size limits which means: messages span chunks, and chunks span blocks.

The simple messages are from the app to the amp, and are usually just one block, one chunk and the data.

Sending a preset, or receiving a preset, is more complex and involves multiple blocks and chunks.

Figure 1 shows the relationship between the blocks, chunks and data that make up the message.

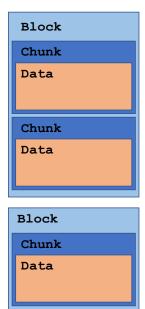

Figure 1

When the app sends a message then the Spark (usually) responds with an acknowledgement message.

Blocks sent to the amp seem to have a maximum size of 0xad.

Blocks sent from the amp seem to have a maximum size of 0x6a.

#### Block format

Each block has a header and then contains the chunk / data.

Offset	Length	Description
0	4	0x01fe0000
4	2	Direction of the message:
		0x41ff - from Spark
		0x53fe - to Spark
6	1	Size of this block (including
		this header)
7	9	Zeros
10		The chunk / data

Figure 2 shows an example of a block header.

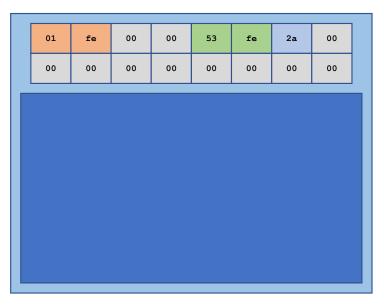

Figure 2

### Chunk format

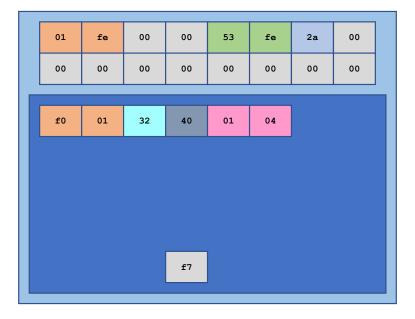

Offset (in block)	Length	Description
10	2	0xf001
12	1	Sequence number
13	1	Unknown
14	1	Command
15	1	Sub-command
16		Data
	1	0xf7

The chunk starts with fixed bytes of 0xf001 and ends with the byte 0xf7. This is very like the MIDI SysEx wrapper of 0xf0 and 0xf7.

The header includes a sequence number which increments with each message (so it remains consistent across chunks and blocks for the same message). When the amp acknowledges a message it contains the sequence number in the acknowledgement message.

The command and sub-command describe what the change is to the amp or from the amp (eg change gain on the amp model).

Figure 3 shows a block header, chunk header and trailer.

### Figure 3

#### Data format

The message is a sequence of variables. Each variable has a distinct pattern which identifies it.

The variables are stored in the data section in sequences of 8 bytes. In the data section bytes have the top bit set to zero, so only carry 7 bits of data. The remaining  $8^{\text{th}}$  bit is packed into another byte which only contains the  $8^{\text{th}}$  bit of each of the bytes in the sequence.

So the format is the special byte containing the  $8^{\rm th}$  bites, followed by seven data bytes.

Figure 4 shows the structure of the sequence – the '8 $^{\rm th}$  bits' byte followed by up to 7 data bytes.

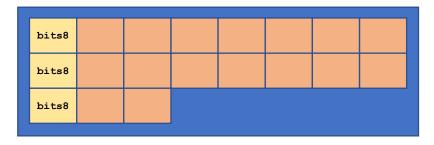

Figure 4

Figure 3 shows an example of the mapping for the missing  $8^{\text{th}}$  bit. In this example, the data in the fourth data byte in the first sequence should have its  $8^{\text{th}}$  bit added back (represented by bit 3 being set in the '8th bits' byte. And the same for the third and sixth bytes in the second sequence (bits 2 and 5 set in the '8th bits' byte.

	0	1	2	3	4	5	6
	1	2	4	8	10	20	40
08				8 <sup>th</sup> bit missing			
24			8 <sup>th</sup> bit missing			8 <sup>th</sup> bit missing	

#### Figure 5

To interpret the data it is therefore essential to add back these bits.

#### Overall structure

Figure 6 shows a representation of the overall structure, including headers, trailers and format bytes. Figure 7 shows an example of the headers and footers.

These both show a single block  $\/$  single chunk message and summarise the description so far.

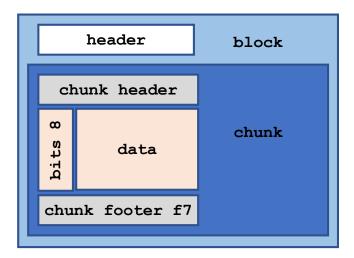

Figure 6

Figure 7

### Variable types

The data format is based on msgpack ( $\underline{www.msgpack.org}$ ).

The data in the message is a set of variables - integers, strings, Booleans and floating-point values.

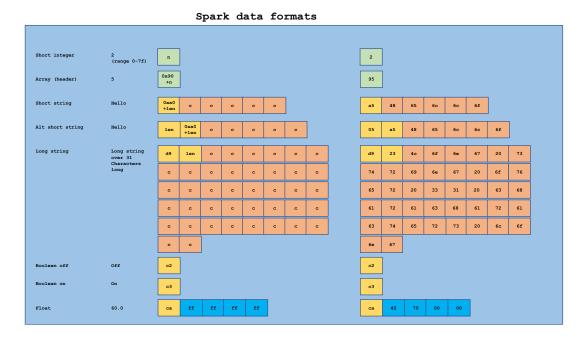

They have no identifiers to describe what they represent.

In many cases it is possible to determine the data type from the first byte. This appears not to work for short integers, which may have a range 0x00-0xff and is not distinguishable from the first byte of the alternative short string and the first byte of an integer. (This is mostly seen in a simple message to change the value of an effect parameter.)

Type	Length	Description	First byte
			range
Short integers	1	Data value from 0x00 to 0x0f?	0x00 - 0x7f
		How is this distinguished from 0x00 as the	
		start of an integer.	
		How is this distinguished from the first	
		byte of the alternative short string?	
Alterative	1	Data value from 0x00 to 0x0f, stored as	0x90-0x9f
short integer		data value + 0x90.	
Integer	2	Data value from 0x00 to 0xff	0x00
		Stored as 0x00 then the data value.	
Short string	n+1	First byte is the length + 0xa0, then the	0xa0 - 0xbf
(1-31		bytes of the string in ASCII encoding	
characters)			
Alternative	n+2	First byte is the length, next byte is the	0x01 - 0x0f
short string		length + 0xa0, then the bytes of the	
(1-31		string in ASCII encoding	
characters)		(Unsure if this is limited to 15	
		characters but it would be logical given	
		the apparent use of the first byte to	
		describe the data type.)	
Long string	n+2	First byte is 0x59, then the length, then	0xd9
		the bytes of the string	
Boolean Off	1	A single byte representing effect Off	0xc2
Boolean On	1	A single byte representing effect On	0xc3

Float	5	A float value - 4 bytes big endian with a	0xca
		preceding byte of Oxca	

Figure 8 shows these data types in a visual format

### Figure 8

Figure 9 shows a completed message, with all headers, footers, data and format bytes.

This is data with a string "LA2AComp", a short integer of 1 and a float represented by 0x3f4d4244.

Figure 9
Figure 10 shows this with explanatory labelling.

01	fe	00	00	dire	ction	block size	00
00	00	00	00	00	00	00	00
f0	01	sequence	???	command	sub- command		
bits 8	08	28	L	A	2	A	С
bits 8	0	m	р	01	4a	3f	4d
bits 8	42	44					
			end				

Figure 10

### Float representation

Floats are based on the 4-byte IEEE-754 encoding. As with all the other data section formats, the bytes are 7-bit only and the missing  $8^{\text{th}}$  bit is in the first byte of any 8 byte sequence.

Figure 11 shows how this works.

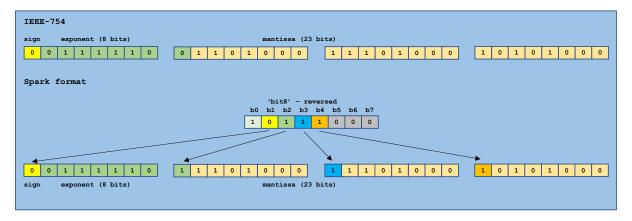

Figure 11

Special values are shown below

# Effects with toggle switches (such as Multi Head delay)

Hex	Float	Special meaning		
00 00 00 00	0.0	False (for a toggle switch)		
3f 00 00 00	0.5	True (for a toggle switch)		

# Digital delay

Hex	Float	Special meaning
3f 00 33 33		1s
3f 06 19 19		500ms
3f 07 4c 4c		200ms
3f 07 19 19		50ms

### Multi Head delay

Hex	Float	Special meaning
3e 4c 4c 01		Head 0 + 2
3e 4c 4c 01		Head 0 + 1 (but the same hex as above?)
3f 19 19 01		Head 1 + 2
3f 4c 4c 01		Head 0 + 1 + 2

### Messages that span chunks and blocks

The only messages large enough to span multiple chunks and blocks are those sending a complete preset, either to or from the amp. They can be identified by the command and sub-command (see later).

In these cases, the first three bytes of the data (excluding the format byte) represent which chunk this is.

The size of the chunks and the data in these bytes depends on the direction of the message.

### Multi-chunk messages sent to the amp

In this case, whilst the message spans multiple chunks, each chunk fills a block. The maximum sending block size is 0xad bytes, so the size of the chunk is 0x9b.

This is calculated as block size - block header - chunk header - chunk trailer (0xad - 0x10 - 0x06 - 0x01 = 0x9b)

The first four bytes of the chunk data are as in the table below - representing the format byte and the multi-chunk sub-header.

Offset	Length	Description
(in		
chunk)		
6	1	First '8th bits' byte
7	1	Total number of chunks
8	1	Reference number of this chunk
		(0 to total number of chunks - 1)
9	1	Size of this chunk (in data bytes which therefore excludes
		counting the '8th bit' bytes, max 0x80)

The number of data bytes remaining is a count of bytes excluding the '8 $^{\rm th}$  bit' bytes.

Figure 12 shows the overall structure of a multi-chunk message sent to the amp.

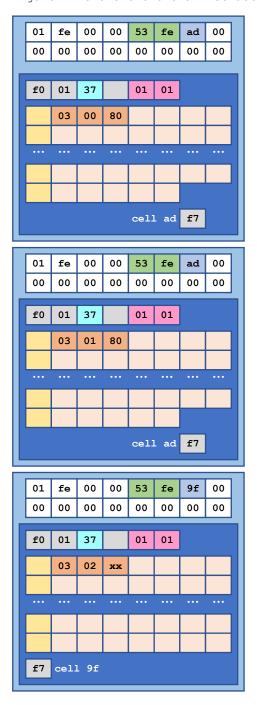

Figure 12

### Multi-chunk messages received from the amp

In this case, whilst the message spans multiple chunks, there are multiple chunks in each block. Each chunk has a maximum size of 0x27 and the block has a maximum size of 0x6a.

The first four bytes of the chunk data are as in the table below - representing the format byte and the multi-chunk sub-header.

Offset	Length	Description
(in		
chunk)		
6	1	First format byte
7	1	Total number of chunks
8	1	Reference number of this chunk
		(0 to total number of chunks - 1)
9	1	For all chunks: Size of this chunk (in useful data bytes, so
		ignoring the '8th bit' bytes)

The number of data bytes remaining is a count of bytes excluding the '8th bit' bytes and is present in each chunk. In all full chunks this is 0x19.

Figure 13 shows the overall structure of a multi-chunk message received from the  $\operatorname{amp}$ .

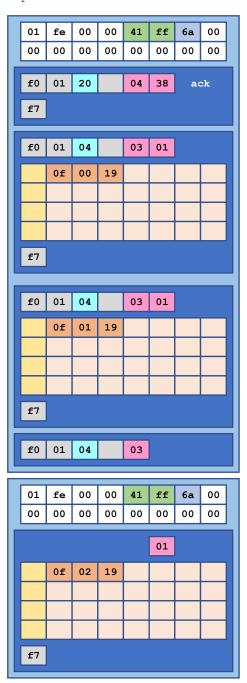

Figure 13

# Commands sent to the amp

These are the commands which can be sent to the amp and the responses expected.

Command	Sub-command	Meaning	Response
01	01	Send preset details to the amp	Acknowledge message
01	04	Send new effect parameter	None
01	06	Change effect to new effect	Acknowledge message
01	15	Enable / disable an effect	Acknowledge message
01	38	Change to a different preset	Acknowledge message
02	01	Get preset details from amp	Acknowledge message followed by preset information
02	11	Get amp name ("Spark 40")	Acknowledge message followed by amp name
02	23	Get amp serial number	
02	24	Unknown	

# Commands sent from the amp

These are the commands  $\slash\$  responses sent from the amp. Response to the amp are  $\slash\$  unknown.

Command	Sub-command	Meaning	Response
03 06		Change of effect (amp model) on	Unknown
		the amp	
03	27	Store current preset in hardware	Unknown
		preset	
03	37	Change of effect parameter on	Unknown
		amp	
03	38	Change of preset selected on the	Unknown
		amp	
03	01	Response to a preset information	Unknown
		query command	
04	As per	Acknowledgement from the amp	
	command	that it received a message.	
	received by		
	amp		

# Detail of commands

# 0x0104 - change effect parameter

Туре	Length	Content	Example
Alternative short string	n+2	Effect name	0x04 0x24 Twin
Short integer	1	Number of the	0x00 (Gain)
		parameter starting at	
		0	
Float	5	Value for the	0x4a
		parameter (0-1.0,	0x3f 0x21 0x72 0x13
		with 1.0 representing	
		10 in the user	
		interface)	

# 0x0106 - swap effects

Туре	Length	Content	Example
Alternative short string	n+2	Old effect name	0x08 0x28 LA2AComp
Alternative short string	n+2	New effect name	0x08 0x28 BlueComp

# 0x0115 - enable / disable effect

Туре	Length	Content	Example
Alternative short string	n+2	New effect name	0x08 0x28 BlueComp
Boolean	1	New status	0x43
		0x42 off	
		0x43 on	

### 0x0138 - change to a new hardware preset

Туре	Length	Content	Example
Integer	2	New preset number	0x00 0x03
		0-3, 0x7f	

### 0x0201 - get preset information

Туре	Length	Content	Example
Integer	2	preset number 0-3 0x7f? 0x100?	0x00 0x03
Short integer	1 x 34	34 bytes of 0x00	0x00

# 0x0211 - get amp name

No data in message for this command  $% \left( 1\right) =\left( 1\right) \left( 1\right) \left($ 

### 0x0223 - get amp serial number

No data in message for this command

### 0x0224 - unknown command

Not known what this command does

Туре	Length	Content	Example
Alternative short	1	0x14	0x14
integer			(4)
Short integer	1	0x00	0x00
Short integer	1	0x01	0x01
Short integer	1	0x02	0x02
Short integer	1	0x03	0x03

# $0 \times 0306$ - change of effect (amp model) on the amp

Туре	Length	Content	Example
Alternative short string	n+2	Old amp name	0x0d 0x2d
			GK800
Alternative short string	n+2	New amp name	0x05 0x25
			Twin

### 0x0327 - current preset stored to hardware on the amp

Туре	Length	Content	Example
Integer	2	Number of the preset	0x00 0x02
		where settings are	(2)
		stored	

### 0x0337 - change of parameter for effect on the amp

Туре	Length	Content	Example
Alternative short string	n+2	Effect name	0x04 0x24
			Twin
Alternative short	1	Parameter number	0x00
integer			(0) (Gain)
			OR
			0x03
			(3) (Bass)
			OR
			0x04
			(4) (Master)
Float	5	New value	0x4a
			0x3e 0x6d 0x5b 0x37

### 0x0338 - change of preset selected on the amp

Туре	Length	Content	Example
Integer	2	Number of the new	0x00 0x02
		preset	(2)

### 0x04nn - acknowledgement

This has command 0x04 and the same sub-command as was issued to the amp. It has the same sequence number as the command issued to the app.

There is no body to this message - just the chunk header and the trailer (0xf7)

# 0x0101 - send preset

A new preset is a multi-chunk message, so the first three bytes of each new chunk are the chunk sub-header.

The preset format contains data for the preset, and then information for each effect - 7 in total.

Each effect contains data for the effect, and then a value for each parameter in the effect.

The final byte of the preset is currently unknown. It could be a checksum but doesn't impact the data sent as the preset.

Туре	Length	Content	Example
Integer	2	If saving to a	0x00 0x7f
		hardware preset	
		location this is 0-3	
		otherwise 0x7f	
Long string	36	UUID of preset	
Short string	n+1	Name	0x2d
			Spooky Melody
Short string	n+1	Version	0x23
			0.7
Short string	n+1	Description	0x37
			Description for
			Alternative Preset 1
Short string	n+1	Icon name	0x28
			icon.png
Float	5	BPM	0x4a
			0x42 0x70 0x00 0x00
			(60.0)
Short integer	1	Number of effects -	0x17
		always 7.	(7)
Effect 0		See below	
Parameter 0		See below	
Parameter 1		See below	
Effect 1		See below	
Parameter 0		See below	
Effect 2		See below	
Effect 3		See below	
Effect 4		See below	
Effect 5		See below	
Effect 6		See below	
Short integer	1	Unknown	

Each effect then has a section describing the effect (7 effects in total)

Туре	Length	Content	Example
Short string	n+1	Effect name	0x08 0x28 BlueComp
Boolean	1	Status	0x43
		0x42 off	(On)
		0x43 on	
Short integer	1	Number of parameters	0x12
		for this effect	(2)

And then each parameter has a section describing the value for the parameter

Туре	Length	Content	Example
Alternative short	n+1	Parameter reference	0x01
integer			(1)
Alternative short	1	Unknown	0x11
integer		0x11	
Float	1	Value for this	0x4a
		parameter	0x3e 0x35 0x55 0x3f

Figure 14 shows this overall structure.

								14	1	16	2	12
				n	n	n	n					
Х	n	n	n	n	n	n	n					
х	n	f7										

### Appendix 4 - TODO

What I still don't understand:

\* What the byte 0x11 is for in each pedal preset.

It is msgpack for an array of size 1! Actually 0x91.

\* Whether the nibble or byte data type really exists

Not in msgpack - it is a range 0x00 to 0x7f.

\* Why the chunk header sometimes contains the count of data bytes remaining (excluding format bytes) and sometimes doesn't

It always does - but sometimes that is 0x80 which is shown as 0x00 in the 7bit / 8bit encodig scheme

 $^{\star}$  What the format bytes are really used for, especially the one in front of the chunk header - it seems to have a special meaning

It is the 7bit/8 bit encoding!

- \* What that final byte is for in the preset a checksum? If so it isn't checked Sometimes MIDI SysEx has a checksum, so probably that
- $\ensuremath{^{\star}}$  What the byte after the sequence byte is for

Still a mystery!

#### Appendix 5 - SysEx 7bit/8bit encoding functions

The best reference I could find is in the Arduino MIDI library and refers to Ruin & Wesen's SysEx encoder/decoder -  $\frac{\text{http://ruinwesen.com}}{\text{moder}}$ 

Sadly this reference is broken so there is no clarity on whether this encoding has a recognised name.

            count.
   return outLength + count + (count != 0 ? 1 : 0);
/*! \brief Decode System Exclusive messages.
SysEx messages are encoded to guarantee transmission of data bytes higher than
127 without breaking the MIDI protocol. Use this static method to reassemble
your received message.
 \param inSysEx The SysEx data received from MIDI in.
 \param outData The output buffer where to store the decrypted message.
 \param inLength The length of the input buffer.
 \param inFlipHeaderBits True for Korg and other who store MSB in reverse order
\return The length of the output buffer.
@see encodeSysEx @see getSysExArrayLength
Code inspired from Ruin & Wesen's SysEx encoder/decoder - http://ruinwesen.com
unsigned decodeSysEx(const byte* inSysEx,
                     byte* outData,
                     unsigned inLength,
                     bool inFlipHeaderBits)
{
   unsigned count = 0;
   byte msbStorage = 0;
   byte byteIndex = 0;
    for (unsigned i = 0; i < inLength; ++i)</pre>
```

```
if ((i % 8) == 0)
{
    msbStorage = inSysEx[i];
    byteIndex = 6;
}
else
{
    const byte body = inSysEx[i];
    const byte shift = inFlipHeaderBits ? 6 - byteIndex : byteIndex;
    const byte msb = byte(((msbStorage >> shift) & 1) << 7);
    byteIndex--;
    outData[count++] = msb | body;
}
return count;
}</pre>
```

### Appendix 6 - msgpack

This format is described at:

www.msgpack.org

https://github.com/msgpack/msgpack/blob/master/spec.md

There are multiple implementations and the python one is obtained by:

#### python -m pip install msgpack

The Spark data is not an exact msgpack implementation because it does not start as an array, and the effect and effect parameters are malformed as arrays.

The data is like this:

```
\x97
\xaebias.noisegate
\xc2
\x93
\x00
\x91
\xca>\r\xa1\xec
\x01
\x91
\xca>f\x08\xd1
\x02
\x91
\xca\x00\x00\x00
```

This should be an array of 7 elements - one for each effect. Then each effect has three values - name, on/off status, an array of parameters - best as a key/value pair except that msgpack doesn't allow integers as keys.

But the array content is like this:

```
['bias.noisegate',
True,
[0, [0.1201], 1],
[0.3314],
2,
[0.0000]
```

Partly because the array is really three entries per pedal, not one, and partly because each parameter is two entries not one.
